Abstract

IceCube has provided the first measurements of the extragalactic high energy astrophysical neutrino flux. The sources of these neutrinos remains unknown. I will first discuss the possibility that they are of galactic origin and show that they are dominantly extragalactic. The most luminous events in the universe are Gamma ray bursts (GRBs) which are relativistic jetted outflows resulting from some supernovae (SNe). GRBs are a promising candidate of high energy cosmic rays and neutrinos despite no direct evidence of a correlation between events and known sources. Some GRBs may be electromagnetically choked emitting only neutrinos. To constrain the properties of GRBs, we assume that choked GRBs are a natural continuation of visible GRBs. This allows for constraints on GRB properties and the fraction of SNe that form jets from IceCube's data.

Gamma Ray Bursts, Supernovae, Neutrinos, and IceCube

Expected distribution from the galaxy

McMillan: 1102.4340

Galactic or extragalactic?

Given that an event is astrophysical, the conditional likelihoods are,

$$\mathcal{L}_{\mathrm{gal}|\mathrm{astro},i}(f_{\mathrm{gal}}) = f_{\mathrm{gal}} \int d\Omega \, \Phi_{\mathrm{gal}}(\Omega) f_{\mathrm{vMF}}(heta,\kappa_i) \,, \qquad \leftarrow \mathsf{IC's} \; \mathsf{psf}$$

$$\mathcal{L}_{ ext{exgal}| ext{astro},i}(f_{ ext{gal}}) = (1-f_{ ext{gal}})rac{1}{4\pi}\,.$$

The likelihood that event i is described by this model is,

$$\mathcal{L}_i(f_{\mathrm{gal}}) = \mathcal{L}_{\mathrm{bkg},i} rac{1}{4\pi} + \mathcal{L}_{\mathrm{astro},i} \left[\mathcal{L}_{\mathrm{gal}|\mathrm{astro},i}(f_{\mathrm{gal}}) + \mathcal{L}_{\mathrm{exgal}|\mathrm{astro},i}(f_{\mathrm{gal}})
ight] \,,$$

and the total likelihood is the product,

$$\mathcal{L}(f_{ ext{gal}}) = \prod_i \mathcal{L}_i(f_{ ext{gal}}) \,.$$

▶ For $E_{dep} > 60$ TeV, we expect < 6 events from backgrounds.

Gamma ray bursts

GRBs are potential UHECR and $\text{HE}\nu$ sources.

- Most luminous events observed.
- Have observed \sim 1000 GRBs.
- Photon measurements \Rightarrow high Γ outflow.
 - Excellent HE particle production candidate.

- Central engine?
 - CCSN.
 - Binary mergers, ...?
- IceCube has strong constraints from spatial + timing correlations.

IC: 1601.06484

CCSN-GRB connection

Mounting evidence that some or all long duration GRBs are associated with CCSNe.

► Theoretical:

Observational:

Paczyński: astro-ph/9710086 Hjorth, Bloom: 1104.2274 Modjaz: 1105.5297 Hjorth: 1304.7736 Margutti, et al.: 1402.6344

 $CCSN + (rotation, B field) \Rightarrow jet.$

Three kinds of jets

The type of the jet determines the particle output:

- Unsuccessful $\Rightarrow \emptyset$.
- Successful but choked $\Rightarrow \nu$'s.
- Successful and visible $\Rightarrow \nu$'s and γ 's.

- Without EM observations, it is possible to write down anything for a choked source.
- ▶ We assume that all jets are drawn from the same distribution.
- We match the high luminosity jets to observations.
- One extra parameter ζ_{SN} : fraction of CCSNe that harbor jets.

GRB model: properties

- Protons accelerated by the central engine following Fermi acceleration.
- Photons are measured to have a non-thermal spectrum.

```
Band, et al.: ApJ, 413, 281
```

```
Amati, et al.: astro-ph/0205230
```

- \blacktriangleright Magnetic fields carry $\sim 10\%$ of the total jet energy.
- ► Jet opening angle is related to the Lorentz boost factor: $\theta_j = 1/\Gamma$ for $\Gamma \le 100$, $\theta_j = 30/\Gamma$ else.

```
Goldstein, et al.: 1512.04464
```

Sonbas, et al.: 1408.3042

Particle physics in jets

- $p\gamma$ interactions lead to pions and kaons.
- Pions and kaons quickly decay to muons and neutrinos.
- Muons decay to more neutrinos.
- Protons, pions, kaons, and muons lose energy in the jet,

Proton cooling

Similarly for π 's, μ 's, and K's.

IIHE: April 4, 2018 18/27

Distribution of jets: the Simple model

Each jet has one Γ value sampled from a power law $\propto \Gamma^{\alpha_{\Gamma}}.$

We normalize with the SN and HL-GRB rates,

- All jets are equal to the fraction of SNe ζ_{SN} that form jets and point at us.
- Relativistic jets (Γ > 200) forms the observed HL-GRB data set.

This leads to exponents $\alpha_{\Gamma} \sim [-1, -3]$ depending on ζ_{SN} .

Then the redshift evolution follows that of star formation rate not that of GRBs.

Yuksel, et al.: 0804.4008

Structured jets: the Advanced model

Multiple shocks \rightarrow random walk.

Distribution of jets drawn from a power law. In each jet:

- $\Gamma = \Gamma_{max}$ along the jet axis.
- ► Γ falls off as the angle increases with characteristic width $\sigma = 1/\sqrt{\Gamma_{\text{max}}}$.
- The total jet opening angle contains all Γ > 1.

The observed distribution in Γ 's comes from both:

- \blacktriangleright Distribution of jets: power law in $\Gamma_{max},$ and
- Angle of the jets relative to the Earth.

Choked fraction

Peter B. Denton NBIA

1802.10098

Low energy GRB diffuse intensity: choked jets?

Choked jets constraints

Conclusions

- ► IceCube has measured the HE astrophysical neutrino flux.
- ► The astrophysical neutrino flux is extragalactic and isotropic.
- GRBs naturally lead to a high neutrino flux.
- Need to consider different classes of jets.
- CCSNe-GRB connection allows for physical constraints on choked GRBs.
- $\blacktriangleright~\lesssim 1\%$ of CCSNe form jets, the majority of which will be choked.
- These could be type Ibc SNe forming jets: unsuccessful, choked, off/on-axis.
- Choked jets don't explain the low energy excess.

Muon energy correction

The energy deposited in tracks is not the true neutrino energy because the muon carries some of the energy out of the detector.

- Muon energy loss rate: $\frac{dE_{\mu}}{d\ell} = -(a + bE_{\mu}).$
- Inelasticity parameter $y \equiv E_{had}/E_{\nu}$.
- ► For a finite sized detector l_{max} = 1 km, we can relate the deposited and neutrino energies by,

$$rac{{\mathcal E}_{
m dep}}{{\mathcal E}_
u}pprox \langle y
angle + ig(1-\langle y
angleig)b\ell_{
m max}\,,$$

which is valid in the region of interest.

Anchordoqui, Weiler, et al.: 1611.07905

•
$$\langle y \rangle \in [0.25, 0.55]$$
 for relevant energies.

Normalization

Normalize to GRB and CCSNe rates based on Γ along line of sight:

- The CCSNe rate times the fraction (ζ_{SN}) that forms jets normalizes all the jets.
- The HL-GRB rate normalizes the highly relativistic jets ($\Gamma > 200$).

This leads to exponents $\alpha_{\Gamma} \sim [-1, -3]$ depending on ζ_{SN} .

The redshift evolution follows that of star formation rate not that of GRBs.
