

Algorithms for computing neutrino oscillation probabilities in sharply varying matter potentials such as the Earth are becoming increasingly important. As the next generation of experiments, DUNE and HyperK as well as the IceCube upgrade and KM3NeT, come online, the computational cost for atmospheric and solar neutrinos will continue to increase. To address these issues, we expand upon our previous algorithm for long-baseline calculations to efficiently handle probabilities through the Earth for atmospheric, nighttime solar, and supernova neutrinos. The algorithm is fast, flexible, and accurate. It can handle arbitrary Earth models with two different schemes for varying density profiles. We also provide a c++ implementation of the code called NuFast-Earth along with a detailed user manual. The code intelligently keeps track of repeated calculations and only recalculates what is needed on each successive call which can also help provide significant speed-ups.

NuFast-Earth

Brookhaven™
National Laboratory

The Problem

$$\begin{array}{c} \Delta m_{21}^2, \Delta m_{31}^2 \\ s_{23}^2, s_{13}^2, s_{12}^2 \\ \delta \end{array}$$

$\Rightarrow$
in (sharply varying) matter

Many Approaches

Modify vacuum probabilities

- ▶ Get the eigenvalues by solving the cubic

Cardano 1545

V. Barger, et al. [PRD 22 \(1980\) 2718](#)

- ▶ Get the eigenvectors

H. Zaglauer, K. Schwarzer [Z.Phys. C40 \(1988\) 273](#)

K. Kimura, A. Takamura, H. Yokomakura [hep-ph/0205295](#)

[PBD](#), S. Parke, X. Zhang [1907.02534](#)

A. Abdulahi, S. Parke [2212.12565](#)

Advantage: can use existing intuition about the parameters

Atmospheric/Solar: Many Approaches

Solve the Schrödinger equation

$$i\frac{d}{dt}|\nu\rangle = H(t)|\nu\rangle$$

For region j where H is approximately constant: H_j (constant density)

$$\mathcal{A}_j = e^{-iH_j L_j} \quad P(\nu_\alpha \rightarrow \nu_\beta) = \left| \left[\prod_j \mathcal{A}_j \right]_{\beta\alpha} \right|^2$$

Exponential requires computing eigenvalues and eigenvectors of H_j ,
for good precision through the Earth, repeat this many times

Fermilab computing experts bolster NOvA evidence, 1 million cores consumed

July 3, 2018 | Marcia Teckenbrock

[Share](#) [Tweet](#) [Email](#)

Array

How do you arrive at the physical laws of the universe when you're given experimental data on a renegade particle that interacts so rarely with matter, it can cruise through light-years of lead? You call on the power of advanced computing.

The NOvA neutrino experiment, in collaboration with the Department of Energy's Scientific Discovery through Advanced Computing (SciDAC-4) program and the HEPcloud program at DOE's Fermi National Accelerator Laboratory, was able to perform the largest-scale analysis ever to support the [recent evidence of antineutrino oscillation](#), a phenomenon that may hold clues to how our universe evolved.

Using Cori, the newest supercomputer at the [National Energy Research Scientific Computing Center \(NERSC\)](#), located at Lawrence Berkeley National Laboratory, NOvA used over 1 million computing cores, or CPUs, between May 14 and 15 and over a short timeframe one week later. This is the largest number of CPUs ever used concurrently over this duration — about 54 hours — for a single high-energy physics experiment. This unprecedented amount of computing enabled scientists to carry out some of the most complicated techniques used in neutrino physics, allowing them to dig deeper into the seldom seen interactions of neutrinos. This Cori allocation was more than 400 times the amount of Fermilab computing allocated to the NOvA experiment and 50 times the total computing capacity at Fermilab allocated for all of its rare-physics experiments. A continuation of the analysis was performed on NERSC's Cori and Edison supercomputers one week later. In total, [nearly 35 million core-hours were consumed by NOvA](#) in the 54-hour period. Executing the same analysis on a single desktop computer would take 4,000 years.

Monte-Carlo Estimates of Statistical Significances

Wilks' theorem is often wrong

At each point in parameter space, simulate the experiment many times

“many” means $\gg 1/p$ for a desired p -value

This is sometimes called Feldman-Cousins

G. Feldman, R. Cousins [physics/9711021](#)

This isn't actually what was novel in the FC paper

Study found most of
the time was spent
computing probabilities

NOvA/T2K are $\sim 3\sigma$ experiments,
but DUNE/HK will be $\gtrsim 5\sigma$ experiments!

DUNE sensitivities require computing
the probabilities “a zillion times”

How to Achieve Speed

1. Avoid costly operations

- ▶ `sin`, `cos` (and inverse functions) are very slow
- ▶ `sqrt` is quite slow, but not as bad as trigs
- ▶ Division is slower than multiplication ($0.2x$ may be faster than $x/5$)
- ▶ Avoid complex numbers: addition: $2\times$, multiplication: $4\times$, division: $> 8\times$

2. Reduce repeated calculations

- ▶ Compute $\frac{L}{4E}$ in the correct units once
- ▶ Compute each of the three $\sin \frac{\Delta m_{ij}^2 L}{4E}$ once

3. Don't perform unnecessary linear algebra computations

All of these are compiler dependent

Eigenvalues are Hard

The eigenvalues in matter λ_i depend on S (and other things):

$$S = \cos \left\{ \frac{1}{3} \cos^{-1} \left[\frac{2A^3 - 9AB + 27C}{2(A^2 - 3B)^{3/2}} \right] \right\}$$

Cardano 1545

where

$$A = \sum \lambda_i = \Delta m_{21}^2 + \Delta m_{31}^2 + a$$

$$B = \sum_{i>j} \lambda_i \lambda_j = \Delta m_{21}^2 \Delta m_{31}^2 + a[\Delta m_{21}^2(1 - |U_{e2}|^2) + \Delta m_{31}^2(1 - |U_{e3}|^2)]$$

$$C = \prod \lambda_i = a \Delta m_{21}^2 \Delta m_{31}^2 |U_{e1}|^2$$

Approximate Eigenvalues

1. Instead, approximate one eigenvalue
 - λ_3 is best because is never parametrically small and easy to approximate
2. From DMP:

$$\lambda_3 \approx \Delta m_{31}^2 + \frac{1}{2} \Delta m_{ee}^2 \left(x - 1 + \sqrt{(1-x)^2 + 4xs_{13}^2} \right)$$

$$x \equiv \frac{a}{\Delta m_{ee}^2} \quad \Delta m_{ee}^2 \equiv \Delta m_{31}^2 - s_{12}^2 \Delta m_{21}^2$$

H. Minakata, S. Parke [1505.01826](#)
[PBD](#), H. Minakata, S. Parke [1604.08167](#)
H. Nunokawa, S. Parke, R. Funchal [hep-ph/0503283](#)

3. Get other two eigenvalues by picking two of A , B , C conditions

Requires one more $\sqrt{}$

The Approximation

- ▶ This is the only approximation used in the entire approach
- ▶ In vacuum the approximation returns to the correct value

Many approximations in the literature are not correct in vacuum limit
See G. Barenboim, [PBD](#), S. Parke, C. Ternes [1902.00517](#)

- ▶ In fact can iteratively improve λ_3 with rapid convergence via Newton's method:

$$\lambda_3 \rightarrow \lambda_3 - \frac{X(\lambda_3)}{X'(\lambda_3)}$$

$$X(\lambda) = \lambda^3 - A\lambda^2 + B\lambda - C = 0$$

- ▶ Precision improvement starts at 10^{-5} for the first step
 - ▶ The improvement is quadratic thereafter
- ▶ One line of code, just loop as many times as desired

Optimal Structure of the Probability for Atmospherics

1. Cannot apply the long-baseline tricks through the Earth
2. Must compute the amplitude in each layer

$$\prod_j \mathcal{A}_j$$

Optimal Structure of the Probability for Atmospherics

3. Work in the tilde basis with θ_{23} and δ pulled out

► Can shift δ from θ_{13} to θ_{23}

$$\begin{pmatrix} 1 & & \\ & c_{23} & s_{23} \\ & -s_{23} & c_{23} \end{pmatrix} \begin{pmatrix} c_{13} & s_{13}e^{-i\delta} \\ & 1 \\ -s_{13}e^{i\delta} & c_{13} \end{pmatrix} R_{12} \rightarrow \begin{pmatrix} 1 & & \\ & c_{23} & s_{23}e^{i\delta} \\ & -s_{23}e^{-i\delta} & c_{23} \end{pmatrix} \begin{pmatrix} c_{13} & s_{13} \\ & 1 \\ -s_{13} & c_{13} \end{pmatrix} R_{12}$$

Optimal Structure of the Probability for Atmospherics

3. Work in the tilde basis with θ_{23} and δ pulled out

► Can shift δ from θ_{13} to θ_{23}

$$\begin{pmatrix} 1 & & \\ c_{23} & s_{23} & \\ -s_{23} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13}e^{-i\delta} & \\ & 1 & \\ -s_{13}e^{i\delta} & & c_{13} \end{pmatrix} R_{12} \rightarrow \begin{pmatrix} 1 & & \\ c_{23} & s_{23}e^{i\delta} & \\ -s_{23}e^{-i\delta} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13} & \\ & 1 & \\ -s_{13} & & c_{13} \end{pmatrix} R_{12}$$

► U_{23} commutes with the matter potential

$$(2E)H_f = U_{23}(\theta_{23}, \delta) \left[R_{13}R_{12} \begin{pmatrix} 0 & & \\ & \Delta m_{21}^2 & \\ & & \Delta m_{31}^2 \end{pmatrix} R_{12}^T R_{13}^T + \begin{pmatrix} a & & \\ & 0 & \\ & & 0 \end{pmatrix} \right] U_{23}^\dagger(\theta_{23}, \delta)$$

$$H_f = U_{23}(\theta_{23}, \delta) \tilde{H} U_{23}^\dagger(\theta_{23}, \delta)$$

Optimal Structure of the Probability for Atmospherics

3. Work in the tilde basis with θ_{23} and δ pulled out

► Can shift δ from θ_{13} to θ_{23}

$$\begin{pmatrix} 1 & & \\ c_{23} & s_{23} & \\ -s_{23} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13}e^{-i\delta} & \\ & 1 & \\ -s_{13}e^{i\delta} & & c_{13} \end{pmatrix} R_{12} \rightarrow \begin{pmatrix} 1 & & \\ c_{23} & s_{23}e^{i\delta} & \\ -s_{23}e^{-i\delta} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13} & \\ & 1 & \\ -s_{13} & & c_{13} \end{pmatrix} R_{12}$$

► U_{23} commutes with the matter potential

$$(2E)H_f = U_{23}(\theta_{23}, \delta) \left[R_{13}R_{12} \begin{pmatrix} 0 & & \\ & \Delta m_{21}^2 & \\ & & \Delta m_{31}^2 \end{pmatrix} R_{12}^T R_{13}^T + \begin{pmatrix} a & & \\ & 0 & \\ & & 0 \end{pmatrix} \right] U_{23}^\dagger(\theta_{23}, \delta)$$

$$H_f = U_{23}(\theta_{23}, \delta) \tilde{H} U_{23}^\dagger(\theta_{23}, \delta)$$

$$\mathcal{A} = \prod_j \mathcal{A}_j = \prod_j e^{-iH_{f,j}L_j} = U_{23}(\theta_{23}, \delta) \left(\prod_j e^{-i\tilde{H}_jL_j} \right) U_{23}^\dagger(\theta_{23}, \delta)$$

$$U_{23}U_{23}^\dagger = \mathbb{1}$$

Optimal Structure of the Probability for Atmospherics

3. Work in the tilde basis with θ_{23} and δ pulled out

► Can shift δ from θ_{13} to θ_{23}

$$\begin{pmatrix} 1 & & \\ c_{23} & s_{23} & \\ -s_{23} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13}e^{-i\delta} & \\ & 1 & \\ -s_{13}e^{i\delta} & & c_{13} \end{pmatrix} R_{12} \rightarrow \begin{pmatrix} 1 & & \\ c_{23} & s_{23}e^{i\delta} & \\ -s_{23}e^{-i\delta} & c_{23} & \end{pmatrix} \begin{pmatrix} c_{13} & s_{13} & \\ & 1 & \\ -s_{13} & & c_{13} \end{pmatrix} R_{12}$$

► U_{23} commutes with the matter potential

$$(2E)H_f = U_{23}(\theta_{23}, \delta) \left[R_{13}R_{12} \begin{pmatrix} 0 & & \\ & \Delta m_{21}^2 & \\ & & \Delta m_{31}^2 \end{pmatrix} R_{12}^T R_{13}^T + \begin{pmatrix} a & & \\ & 0 & \\ & & 0 \end{pmatrix} \right] U_{23}^\dagger(\theta_{23}, \delta)$$

$$H_f = U_{23}(\theta_{23}, \delta) \tilde{H} U_{23}^\dagger(\theta_{23}, \delta)$$

$$\mathcal{A} = \prod_j \mathcal{A}_j = \prod_j e^{-iH_{f,j}L_j} = U_{23}(\theta_{23}, \delta) \left(\prod_j e^{-i\tilde{H}_jL_j} \right) U_{23}^\dagger(\theta_{23}, \delta)$$

$\tilde{H}$ is real! And doesn't depend on θ_{23} or δ

Reduces many unnecessary computations

$$U_{23}U_{23}^\dagger = \mathbb{1}$$

Further Reductions

- Calculate eigenvalues λ_i : exactly or approx with Newton corrections

Same as in NuFast-LBL

- Further unitarity reductions:

$$\mathcal{A}_{\alpha\beta} = \delta_{\alpha\beta} + V_{\alpha 2} V_{\beta 2}^* (e^{-i\Delta\lambda_{21}L/(2E)} - 1) + V_{\alpha 3} V_{\beta 3}^* (e^{-i\Delta\lambda_{31}L/(2E)} - 1)$$

- In the tilde basis, the $\tilde{V}\tilde{V}^*$ terms are real
- Use adjugate matrices and advanced Eigenvector-Eigenvalue Identity

PBD, S. Parke, T. Tao, X. Zhang [1908.03795](#)
A. Abdulahi, S. Parke [2212.12565](#)

$$\tilde{V}_{\alpha i} \tilde{V}_{\beta i} = \frac{\text{Adj}[\lambda_i \mathbb{1} - (2E)\tilde{H}]}{\prod_{k \neq i} (\lambda_i - \lambda_k)}$$

Earth Trajectories

- ▶ Various Earth density profiles
- ▶ Varying or constant density in each shell

Trajectory goes from:

1. Production height to surface
2. Surface to detector depth
3. Detector depth to deepest point
4. Deepest point to detector depth:
this is the transpose of #3

Example Earth Model

Many Earth models coded up

```
// Earth.cpp
PREM_Prob3::PREM_Prob3()
{
    n_discontinuities = 4;
    discontinuities.reserve(n_discontinuities);
    discontinuities[0] = 1220.;
    discontinuities[1] = 3480.;
    discontinuities[2] = 5701.;
    discontinuities[3] = 6371.;
    Ye = 0.5;
    constant_shells = true;
}

double PREM_Prob3::rhoYe(double r) // g/cm^3
{
    assert(r >= 0);
    if (r > 6371.) return 0.;
    if (r > 5701.) return Ye * 3.3;
    if (r > 3480.) return Ye * 5.;
    if (r > 1220.) return Ye * 11.3;
    return Ye * 13.;
}
```

- ▶ `PREM_NDiscontinuityLayer` takes four integers indicating the number of layers in each major region: inner core, outer core, inner mantle, and outer mantle
`PREM_NDiscontinuityLayer earth_density(2, 10, 10, 5);`

Can also take one integer and apply that to each of the four regions

- ▶ `PREM_NUniformLayer` takes one integer splitting the whole Earth into N layers

Can struggle near sharp boundaries

- ▶ `PREM_Prob3` Four constant layers matching `prob3` code
- ▶ `PREM_Full` Uses **averaging** across major regions
- ▶ `PREM_Four` Same as `PREM_Full` but only has four total regions ignoring the small fluctuations near the surface

Two Earth Model Calculation Techniques

Constant shells:

1. Contains some number of discrete layers
2. Eigenvalue and eigenvector computations: $N_{\text{layer}} \times N_E$
3. Good if there are many energy and zenith angles

Averaging over varying shells:

1. (Typically) uses only several (4 or 10) major regions
2. Computes the average density in each region for each trajectory
3. Handles the fact that e.g. a trajectory through the middle of the core sees a larger average inner core density than one that skims the inner core
4. Eigenvalue and eigenvector computations: $N_{\text{layer}} \times N_E \times N_{\cos \theta_z}$
But may achieve accuracy with smaller N_{layer} ?

In general we find that the averaging approach is not beneficial

Atmospheric Results: NO

Atmospheric Results: IO

Atmospheric Results: Detector Depth: NO

Atmospheric Results: Detector Depth: IO

Atmospheric Results: Detector Depth: Summary

$\max \Delta P $	$\nu_\mu \rightarrow \nu_\mu$		$\nu_\mu \rightarrow \nu_e$	
	ν	$\bar{\nu}$	ν	$\bar{\nu}$
NO	5.1%	5.1%	1.5%	0.2%
IO	5.4%	5.4%	0.3%	1.5%

NuFast-Earth Solar Neutrino Validation

Analytically understand the small deviation at high energy

Nighttime Solar Neutrinos

At night solar neutrinos experience partial regeneration:
There are more ν_e 's from the Sun at night than during the day!

SuperK has $\sim 2\sigma$ evidence for this effect; DUNE and HK aim to measure it well

Solar and Supernova Neutrinos

We compute and provide code for:

- ▶ The Hamiltonian at a given production density
 - ▶ This is just the eigenvectors at the Sun's density
 - ▶ From here it is trivial to compute the day time solar neutrino oscillation probability
- ▶ The nighttime probability
- ▶ The annual averaged weight function

We do not provide code for:

- ▶ The solar model

Supernova neutrinos through the Earth

- ▶ Set production density very high: `Set_rhoYe_Sun(1e6)`

NuFast-Earth Precision

Two approximations:

“True” has exact eigenvalues and 1M layers

Calculate $|\Delta P|$ across 100×100 grid in energy and angle

NuFast-Earth Speed

nuSquIDS takes $>1\text{M}$ ns per trajectory

C. Argüelles, J. Salvado, C. Weaver [2112.13804](#)

OscProb takes 40 000 ns per trajectory at 44 layers (compare to 6000 ns or 200 ns)

J. Coelho, R. Pestes, et al. github.com/joaoabcoelho/OscProb

Other codes are designed with different goals in mind

NuFast-Earth Speed Example of Caching

Ingredients

1. 44 layer Earth
2. Single core-crossing trajectory: $\cos \theta_z = -1$
3. 100 Δm_{31}^2 points and 100 θ_{23} points

Run time:

1. OscProb:

$$100 \times 100 \times (4 \times 10^4 \text{ ns}) = 0.4 \text{ s}$$

2. NuFast-Earth wrong order (loop Δm_{31}^2 first):

$$100 \times 99 \times (6 \times 10^3 \text{ ns}) + 100 \times (2 \times 10^2 \text{ ns}) = 0.06 \text{ s}$$

3. NuFast-Earth right order (loop θ_{23} first):

$$100 \times (6 \times 10^3 \text{ ns}) + 100 \times 99 \times (2 \times 10^2 \text{ ns}) = 0.002 \text{ s}$$

NuFast-Earth Speed: Grid

Number of eigenvalue and eigenvector computations: $N_{\text{layer}} \times N_E$

Time per Earth layer for one core-crossing trajectory:

- ▶ 100 energy by 1 zenith grid (solid)
- ▶ 100 zenith by 1 energy grid (dashed)

Zenith angle bins $\sim 2\times$ faster than energy bins

Cost of computing eigenvalues and eigenvectors comparable to converting to amplitudes and multiplying matrices (which also depend on L and thus $\cos \theta_z$)

NuFast-Earth Fast Parameters

Four fast parameters for insides of loops:

- ▶ θ_{23} : `Set_s23sq`
- ▶ δ : `Set_delta`
- ▶ Production height: `Set_Production_Height`
- ▶ Density at production in Sun/supernova: `Set_rhoYe_Sun`

Also zenith grid points are $\sim 2\times$ faster than energy grid points

NuFast-Earth Flow

```
// Initialize the engine
Probability_Engine probability_engine;

// Set the oscillation parameters to nu-fit 6 best fit
// values:
probability_engine.Set_Oscillation_Parameters(0.307,
0.02195, 0.561, 177 * M_PI / 180, 7.49e-5, 2.534e-3,
true); //(s12sq, s13sq, s23sq, delta, Dmsq21, Dmsq31,
neutrino_mode)

// Set energy and zenith angle arrays
std::vector<double> energies = {1, 2, 3, 4, 5}; // GeV
std::vector<double> coszs = {-1, -0.5, 0, 1}; // core-
crossing to horizontal to down-going
probability_engine.Set_Spectra(energies, coszs);

// Create Earth model instance
PREM_ND discontinuityLayer earth_density(2, 10, 10, 5); //
2 layers in the inner core, 10 layers in the outer
core, 10 layers in the inner mantle, and 5 layers in
the outer mantle
// Set Earth details
probability_engine.Set_Earth(2, &earth_density); //
detector depth in km
// Set production height (optional)
probability_engine.Set_Production_Height(10); // km,
recalculations after changing this are fast

// Do the calculations
std::vector<std::vector<Matrix3r>> probabilities =
probability_engine.Get_Probabilities();
```

Dashed boxes = fast!

NuFast-Earth Recommendations

Many choices in how to use NuFast-Earth
What is the best way for most cases?

1. Eigenvalue precision: set the number of Newton-Raphson corrections to 1
`probability_engine.SetEigenvaluePrecision(1);`
2. Earth model for typical run: 2, 10, 10, 5 layers in each of the four main zones
`PREM_NDiscontinuityLayer earth_density(2, 10, 10, 5);`
3. Looping order: put θ_{23} , δ , and production height on the innermost loops
4. More zenith and fewer energy grid points to achieve desired precision

Summary

- ▶ Computing neutrino oscillations fast is important
- ▶ Atmospheric code is *fast*, if implemented correctly
 - θ_{23} , δ , production height, Sun/SN density are key “fast” parameters
- ▶ Approximate λ_3 and rapid convergence, if desired
- ▶ Get all eigenvalues from λ_3 via A , B , C
- ▶ Pull out θ_{23} and δ for caching
- ▶ Use adjugate algorithm for eigenvectors
- ▶ Structure the Earth trajectory carefully
- ▶ Speed up of 2-3 orders of magnitude

LBL code is already implemented by Daniel Barrow in
NuOscillator $\rightarrow$ **MaCh3** & **GUNDAM**

Scope

1. All 9 channels ($\nu_\alpha \rightarrow \nu_\beta$)
 - ▶ Atmospherics include ν_τ appearance
 - ▶ $\nu_\tau \rightarrow \nu_\beta$ channels are not needed, but come from free from unitarity
2. Different energies, zenith angles, and Earth models
3. Production height, detector depth
4. ν and $\bar{\nu}$
5. NO and IO
6. Oscillation parameters are mostly known
 - ▶ Don't need to consider e.g. $\Delta m_{21}^2 > |\Delta m_{31}^2|$ or $\theta_{23} \sim 10^\circ$

All 9 Channels

Given P_{ee} , $P_{\mu\mu}$, $P_{\mu e}^{TC}$, and $P_{\mu e}^{TV}$:

	$P_{\alpha e}$	$P_{\alpha\mu}$	$P_{\alpha\tau}$
$P_{e\beta}$	P_{ee}	$P_{\mu e}^{TC} - P_{\mu e}^{TV}$	$1 - P_{ee} - P_{\mu e}^{TC} + P_{\mu e}^{TV}$
$P_{\mu\beta}$	$P_{\mu e}^{TC} + P_{\mu e}^{TV}$	$P_{\mu\mu}$	$1 - P_{\mu\mu} - P_{\mu e}^{TC} - P_{\mu e}^{TV}$
$P_{\tau\beta}$	$1 - P_{ee} - P_{\mu e}^{TC} - P_{\mu e}^{TV}$	$1 - P_{\mu\mu} - P_{\mu e}^{TC} + P_{\mu e}^{TV}$	$-1 + P_{ee} + P_{\mu\mu} + 2P_{\mu e}^{TC}$

Optimal Structure of the Probability for Long-Baseline

1. Amplitude requires four trig functions of kinematic variables $(\Delta m_{ij}^2 L/4E)$ ✗
2. Writing the probabilities out requires three trig functions ✓
3. Disappearance structure is straightforward:

$$P_{\alpha\alpha} = 1 - 4 \sum_{i>j} |V_{\alpha i}|^2 |V_{\alpha j}|^2 \sin^2 \frac{\Delta\lambda_{ij}L}{4E}$$

H in matter has eigenvalues λ_i and eigenvectors $V_{\alpha i}$

Optimal Structure of the Probability for Long-Baseline

4. Appearance structure:

T conserving:

$$P_{\mu e}^{TC} = 2 \sum_{i>j} (|V_{\tau k}|^2 - |V_{\mu i}|^2 |V_{ej}|^2 - |V_{\mu j}|^2 |V_{ei}|^2) \sin^2 \frac{\Delta\lambda_{ij}L}{4E}$$

Fun fact:

$$\begin{aligned} & 2\Re(V_{\alpha i} V_{\beta j}^* V_{\alpha j}^* V_{\beta i}) \\ &= |V_{\alpha k}|^2 |V_{\beta k}|^2 - |V_{\alpha i}|^2 |V_{\beta i}|^2 - |V_{\alpha j}|^2 |V_{\beta j}|^2 \\ &= |V_{\gamma k}|^2 - |V_{\alpha i}|^2 |V_{\beta j}|^2 - |V_{\alpha j}|^2 |V_{\beta i}|^2 \end{aligned}$$

T violating:

$$P_{\mu e}^{TV} = -8J \frac{\Delta m_{21}^2 \Delta m_{31}^2 \Delta m_{32}^2}{\Delta\lambda_{21} \Delta\lambda_{31} \Delta\lambda_{32}} \sin \frac{\Delta\lambda_{21}L}{4E} \sin \frac{\Delta\lambda_{31}L}{4E} \sin \frac{\Delta\lambda_{32}L}{4E}$$

P. Harrison, W. Scott [hep-ph/9912435](#)

Account for Matter in Long-Baseline

1. Need the eigenvalues λ_i
2. For eigenvectors, naively need $\Re(V_{\alpha i} V_{\beta j}^* V_{\alpha j} V_{\beta i})$
3. Given our form, need only the $|V_{\alpha i}|^2$ and J in vacuum
 - Don't need any phase information of the eigenvectors!

Leverages [PBD](#), S. Parke, X. Zhang [1907.02534](#)

4. Can compute the $|V_{\alpha i}|^2$ from the λ_i and submatrix eigenvalues (requires only a square root) using Eigenvector-Eigenvalue Identity

$$|V_{\alpha i}|^2 = \frac{\prod_{k=1}^{n-1} (\lambda_i - \xi_k^\alpha)}{\prod_{k=1; k \neq i}^n (\lambda_i - \lambda_k)}$$

See e.g. [PBD](#), S. Parke, T. Tao, X. Zhang [1908.03795](#)
Can actually avoid the $\sqrt{}$ in practice

Total LBL Approach

1. Inputs: 6 oscillation parameters, experimental details (L , E , ρ , Y_e)
2. Calculate λ_3 approximately
 - ▶ Iteratively improve with Newton's method, if desired
3. Calculate the $|V_{\alpha i}|^2$'s with the Eigenvector-Eigenvalue Identity
4. Calculate the sines of the kinematic terms
5. Calculate the T violating term with the NHS identity
6. Calculate key probabilities: P_{ee} , $P_{\mu\mu}$, and $P_{\mu e}$
7. Calculate remaining probabilities

LBL Precision

Is this approximation okay?
DUNE requires $\lesssim 1\%$ level precision

Slightly better for HK
 $\sim 10^{-10}$ for JUNO
See backups

LBL Speed

Is this algorithm fast?
How does it compare?

- ▶ “Conservative” = default, -O0
- ▶ “Aggressive” = -Ofast and -ffast-math
- ▶ Some variation expected due to architecture

See also J. Page [2309.06900](#)
and P. Huber, et al. [hep-ph/0701187](#)

NuFast-LBL: the Code

- ▶ Code is on github: github.com/PeterDenton/NuFast-LBL
- ▶ Implementations in c++ and f90
- ▶ Easy to use and there are comments!

```
// NuFast.cpp
// Calculate the probabilities:
Probability_Matter_LBL(s12sq, s13sq, s23sq, delta,
    Dmsq21, Dmsq31, L, E, rho, Ye, N_Newton,
    &probs_returned);
// Print out the probabilities to terminal
for (int alpha = 0; alpha < 3; alpha++)
{
    for (int beta = 0; beta < 3; beta++)
    {
        printf("%d %d %g\n", alpha, beta,
            probs_returned[alpha][beta]);
    } // beta, 3
} // alpha, 3
```

- ▶ $\bar{\nu}$: $E < 0$; IO: $\Delta m_{31}^2 < 0$
- ▶ Folder called Benchmarks to make the plots in the paper
- ▶ Used in [NuOscillator](#), [MaCh3](#), and [GUNDAM](#)

NuFast-Earth LBL Validation
